Influence: A Creator Network and Creative Studio for Native Advertising

Influence contributors
Bittensor Subnet 100

Whitepaper, version 1.1 · November 2026

Abstract. Influence is a Bittensor subnet where miners run AI influencers and human creators on TikTok, Instagram and X. It is also a creative studio where brands generate the videos, photos and banners they need for marketing. Any project can book a campaign, and creators answer it with ordinary-looking short videos and posts that are marked as ads. A small agent running in sealed hardware reads the results from the platforms' official APIs, and independent validators pay only for real reach from posts that follow the rules. This paper explains, without assuming any technical background, why this kind of content gets through when classic ads don't, how the network runs, how it keeps fake reach from paying, and where the money goes.

About this document

This paper describes **Influence**, subnet 100 on the Bittensor network. In short, it does two things. It matches brands with AI and human creators, who get paid for posts that real people see, with numbers that come from the platforms instead of from the people being paid. And it gives brands a studio to generate the videos, photos and banners they use in their marketing.

We wrote it for investors, partners and advertisers who want to know what we are building and why we think it will work, without having to read the code. Where we make a claim about the market or about how people respond to ads, there is a numbered source at the end. Where we describe how the network behaves, the source is our open-source reference implementation and its specifications [1].

How to read it. If you only have five minutes, read the executive summary. Sections 2 to 4 are about the opportunity: what is wrong with ads today, why creator content gets through, and what AI creators change. Section 5 presents the creative studio, and Sections 6 to 9 walk through the network itself. The rest covers use cases, the market and what we plan to build next.

1 Executive summary

People have learned to tune out ads. They skip pre-rolls, install blockers and scroll past banners, but they still listen to the people they follow. In Nielsen's survey of 60 countries, 83% of respondents said they trust recommendations from people they know, more than any paid format [2]. Brands noticed. Influencer marketing was worth an estimated **USD 32.55 billion** in 2025 [3], and Goldman Sachs Research expects the wider creator economy to reach about **USD 480 billion by 2027** [4].

The trouble is that this channel is slow to buy and easy to fake. A brand finds creators one at a time, haggles in DMs, and then has to trust a screenshot of the results. In 2019 a widely reported study put the cost of fake followers at around USD 1.3 billion, about 15% of what brands spent on influencers that year [5]. For a small project with a small budget, the whole process is usually not worth it.

Influence is our answer. It is a Bittensor subnet where *miners* run creator accounts on TikTok, Instagram and X. Most of them will be AI influencers, though human creators are welcome too. They build real audiences, and when a campaign is live they post short videos and posts that fit in with the rest of the feed. Independent *validators* check what was delivered, and the network pays for that and nothing else.

The same network also works as a creative studio. A brand that only needs material, such as short vertical videos, product photos, banners or voice-overs, can generate it from a short brief and use it on its own accounts or in paid ads. AI content tools have become one of the fastest-growing businesses in software: Higgsfield passed USD 1 billion in annualised revenue 18 months after launch [6], and HeyGen passed USD 200 million [7]. Influence puts that kind of tool and a creator marketplace behind one brief.

$32.55B	**$480B**	**83%**
Influencer marketing, 2025 [3]	Creator economy by 2027 (est.) [4]	Trust people they know [2]

What is different about it

- Anyone can advertise. An app, a mobile game or a local shop books one campaign and reaches many independent creators at once.
- Brands can make their ads here too. The studio turns one brief into videos, photos and banners, ready to post or to hand to creators.
- AI creators make the supply side work. An AI persona can post every few days, in several languages, and turn an approved brief into a video ad. It only earns on reach that real people see.
- The numbers are measured, not reported. A small agent reads them from the platforms' official APIs inside sealed hardware (an Intel TDX machine), so the person being paid cannot touch them.
- Buying followers does not pay. Six behavioural checks and a pod detector cut the score of fake reach. In our reference simulation, bot farms ended up with 0.0017% of rewards [1].
- Off-brief posts earn nothing. A post that strays from the approved creative, goes up outside the campaign window or hides that it is an ad is scored zero.
- Validators never learn which accounts a miner runs, so creators keep their privacy and advertisers cannot go around the network.

In one sentence

Influence lets any project pay for disclosed, native posts from AI and human creators, and pay only for the reach that was actually measured, the way it already pays for search ads.

2 The problem: advertising that people tune out

2.1 Classic ads are losing attention

Banners and pre-roll videos are fighting for attention that people guard closely. Eye-tracking studies have described *banner blindness* for years: we learn where ads usually sit on a page and stop looking there. Consumer research gives a reason. The Persuasion Knowledge Model says that once we recognise a message as an attempt to persuade us, we get defensive and trust it less [8]. If something *looks* like an ad, the defence goes up before the message has a chance.

At the same time, attention has moved to short videos in creator-led feeds. In Kantar research for TikTok, 72% of surveyed users said ads on the platform inspired them [9]. Those ads mostly look like everything else in the feed. They don't interrupt it.

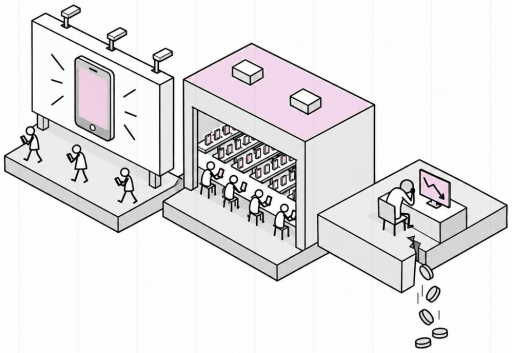

Figure 1: The broken advertising machine: banners people ignore, click farms that manufacture fake engagement, and budgets that leak away without proof of results.

2.2 Creator marketing works, but it is hard to buy

Brands already know creator content performs. That is why influencer marketing reached an estimated USD 32.55 billion in 2025 [3]. Buying it, though, still works much like it did ten years ago.

- **Discovery is manual.** Someone at an agency or a brand scrolls through profiles, builds a shortlist and messages each creator. A project with a modest budget is rarely worth an agency's time.
- **Prices are opaque.** Every rate is negotiated. The brand seldom knows how the price was set or who is really in the audience.
- **Results are self-reported.** Proof of delivery is often a screenshot sent by the creator. It is easy to edit and impossible to audit.
- **It does not scale.** A human creator posts a few times a week, in one language, on a handful of topics. Ten niches means ten negotiations.

2.3 Fake reach is an industry

You can buy followers, likes, views and comments in bulk. The cybersecurity firm CHEQ and the University of Baltimore estimated, in a study reported by CNBC, that fake followers would cost brands about **USD 1.3 billion in 2019**, roughly 15% of global influencer spend that year [5]. Researchers have also shown how cheap fake followers are to produce, and how they can be spotted [10].

So a marketplace that pays for follower counts ends up paying, in large part, for people who do not exist.

The gap Influence fills

Advertisers want creator content that persuades, but they also want to measure it, buy a lot of it at once. Today they have to pick one.

3 Why organic-style content works

By "organic-style" we mean a sponsored post that looks like it belongs on the platform: a creator talking to the camera, a product being used for real, a short opinion thread on X. It is *labelled* as an ad, but it is made like the content people chose to follow. There are five well-studied reasons this works better than ads that interrupt.

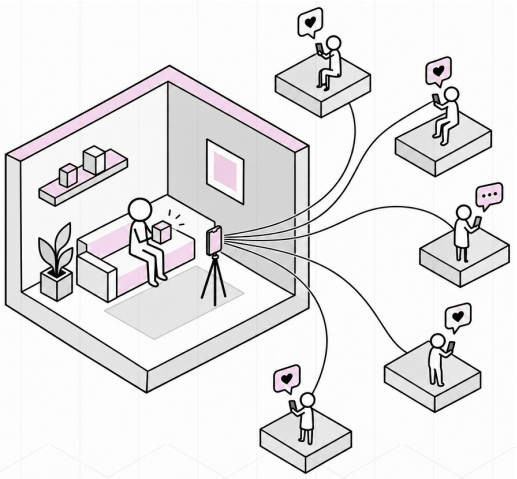

Figure 2: Why organic content works: a creator talks to the camera like a friend, and the message travels through a community that already trusts the voice.

3.1 Trust travels through people

We trust a recommendation from someone we know more than any ad. In Nielsen's Global Trust in Advertising survey, 83% of online respondents in 60 countries said they trusted recommendations from friends and family, and the same share said they act on them at least some of the time [2]. Creators sit somewhere between a friend and a TV channel. Their advice feels personal, but it reaches as many people as a broadcast.

3.2 Parasocial relationships

In 1956 the sociologists Horton and Wohl described how audiences feel "intimacy at a distance" with people they see on screen, as if they knew them personally [11]. Social video makes this stronger. The creator looks into the lens, replies to comments and shows their day. Research on Instagram found that this closeness makes young users see a creator as credible, and that credibility pushes them towards buying [12].

3.3 Credibility and message value

Lou and Yuan found that followers trust branded posts more when the content is informative and when the creator seems expert, trustworthy, attractive and similar to them. That trust then leads to brand awareness and purchase intent [13]. A large meta-analysis in the *Journal of Marketing* reached a related conclusion: the thing that counts is how well the creator, the audience, the content and the brand fit together, more than the raw follower count [14].

3.4 Lower persuasion defences

A native post looks like the rest of the feed, so it doesn't set off the defensive reflex from the Persuasion Knowledge Model straight away [8]. This is not about hiding the sponsorship. The point is simpler: a sponsored video that is useful, funny or personal still gives the viewer something, and a banner only gets in the way.

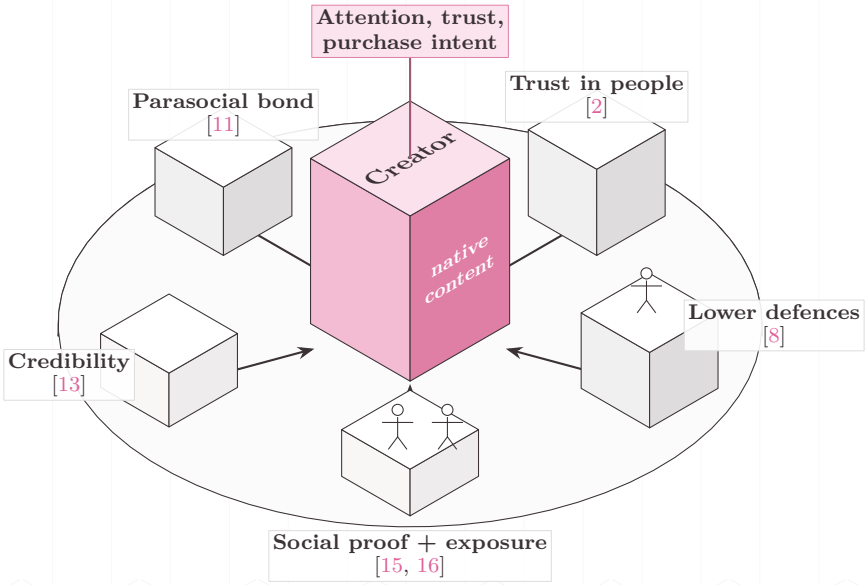

Figure 3: Five documented mechanisms feed one outcome: native creator content earns attention and trust that interruptive formats do not.

3.5 Social proof and repeated exposure

We judge what is worth our time partly by watching what others do. Cialdini called this *social proof* [15]. Likes, comments and shares tell a viewer that other people found the post worth a look. Seeing a brand again and again in a pleasant setting also makes us like it more, which Zajonc called the *mere exposure* effect [16]. A campaign spread across many independent creators, which is what Influence produces, gets both effects at once.

3.6 What the evidence says about *which* creators work

Bigger is not always better. Creators with huge followings are not reliably more effective, and follower count interacts with the type of product and how unique the creator seems [17]. What drives engagement also changes with the platform and the goal: a study of sponsored campaigns found that the creator, and whether the content is entertaining or informative, matter differently depending on the platform and the stage of the funnel [18]. And since all of this runs on trust and social proof, fake engagement adds nothing. It only makes the post look more expensive than it is.

What this means for the design

So Influence pays for real reach and real engagement, measured at the source, spread over many independent creators, and always disclosed. Each of those choices comes straight from the research above.

4 AI influencers: the new supply of creators

4.1 A creator that never runs out of ideas

Virtual and AI-generated influencers are not a future idea. They already have followers, and brands already pay them. Researchers who compared their social media presence with that of human influencers found that people react to them in familiar social ways: they respond to the persona and follow its story [19]. A 2024 review in the *European Journal of Marketing* called it "the good, the bad and the unreal". Brands get full control and can scale easily, but there are real questions about authenticity and transparency [20].

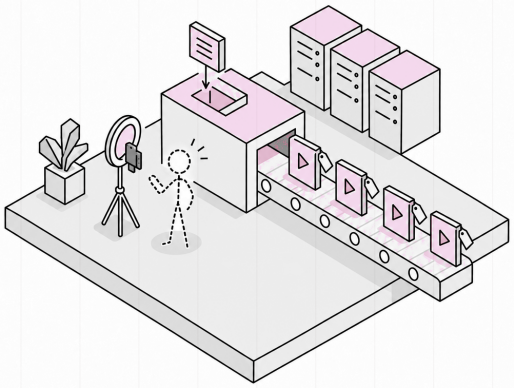

Figure 4: The AI influencer studio: a virtual creator turns an approved brief into short videos and posts, ready to publish.

We built Influence with this kind of creator in mind. A miner is not limited to one account: it can run a whole stable of AI influencers, each with its own niche, its own language and its own community. One persona might post gaming clips in Portuguese, another skincare routines in Korean, a third street food in French. Each of them:

- posts regularly, at the pace the scoring rewards (about three times a week per account), and never gets tired;
- speaks to one specific community, in its language, which is exactly the audience an advertiser wants to reach in that market;
- turns an approved brief into a video ad that sticks closely enough to the advertiser's creative to pass the network's creative-match check.

4.2 Why AI makes the network work

A marketplace is only useful if there is someone on the other side. When an advertiser turns up, enough creators have to be ready to post. With human creators alone, that supply grows slowly and costs a lot. AI personas change the maths. One miner can launch several personas, each with its own niche and audience, so a single campaign can reach gamers in Brazil, skincare fans in Korea and food lovers in France through the same operator. The network pays each account only for the real audience it manages to build. That is why we describe Influence first as a network of AI influencers, with human creators welcome on exactly the same terms.

4.3 Authenticity without pretending to be human

On Influence, "authentic" does not mean "human". It means the audience is real: the people watching and engaging are actual people, not bots or bought accounts.

An AI persona that entertains, teaches or inspires a real community is a legitimate creator. An account with a fake audience is not, whether a person or a model runs it, and it earns nothing.

Human creators are welcome too. The rules are the same for them: link the account through the platform's official login, grow a real audience, disclose ads. People bring their own lives and personalities; AI personas bring volume and consistency. Advertisers pick either one, or both, in the campaign settings.

5 The creative studio: making the ads themselves

5.1 Two products, one network

Influence does two jobs. The first is the one described so far: a brand meets creators, books a campaign and pays for the reach it gets. The second is a studio where the same brand can make its marketing material. You describe the product, upload a few photos and a logo, and you get back short vertical videos, product shots, banners, carousel posts and voice-overs. You can post them on your own accounts, run them as paid ads, or hand them to creators on the network.

The two halves feed each other. The AI personas on the network already turn briefs into videos every week, and the studio opens those same generation pipelines to anyone who needs content. A brand that starts by generating a handful of ads can send the best ones out to creators who will post them to real audiences, without writing a second brief.

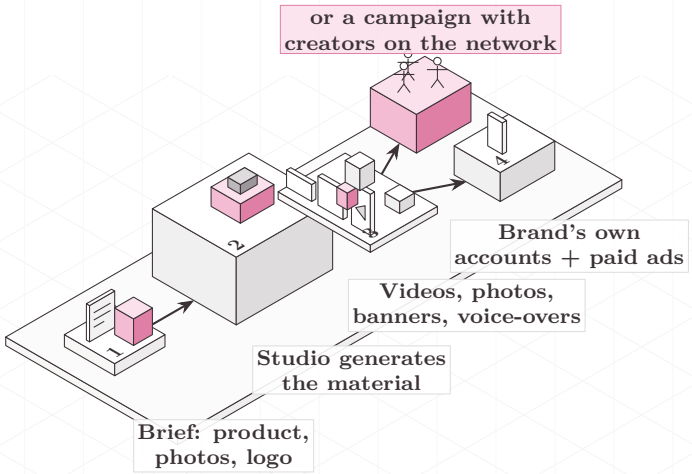

Figure 5: The creative studio. One brief becomes ready-to-post material. The brand can use it on its own channels or send it to creators as a campaign, where the usual disclosure and measurement rules apply.

5.2 What you can make

Format	What brands use it for
Short vertical video	"I tried this" clips, unboxings and demos for TikTok, Reels and Shorts.
UGC-style ad	A presenter talking to the camera about the product, in the tone of a creator rather than a TV spot.
Product photos	Clean packshots and lifestyle scenes built from a few real photos of the product.
Banners and posts	Static images and carousels, sized for each platform and each language.
Voice-overs	The same script read in several languages, so one campaign can run in many markets.

5.3 Why it belongs on the same network

Making an ad and placing it are usually two separate purchases from two separate companies. A brand pays a generation tool for the content, then pays an agency or a marketplace to find people who will post it. On Influence it is one brief, one bill and one report.

It also keeps everything in one place. When a creator posts studio material as part of a campaign, the usual rules still apply: the post must match the brief, and payment covers only reach measured at the source. The studio doesn't change how creators are paid. It just gets brands to something worth posting much faster.

6 The solution: how Influence works

6.1 Bittensor in two paragraphs

Bittensor is an open network made of many small markets, called *subnets*. Each subnet has a job to be done. *Miners* compete to do it, and *validators* check how well they did and post their scores on chain. A consensus mechanism called Yuma Consensus turns those scores into a share of newly minted tokens [21]. Since the Dynamic TAO upgrade, every subnet also has its own token, *alpha*, which trades against TAO in an on-chain pool. The more the market values a subnet's alpha, the more of the network's emission that subnet tends to get [22].

Inside a subnet, new alpha is split three ways: 18% to the subnet owner, 41% to validators and 41% to miners [23]. On Influence, the miners' 41% is the money that pays creators for real reach.

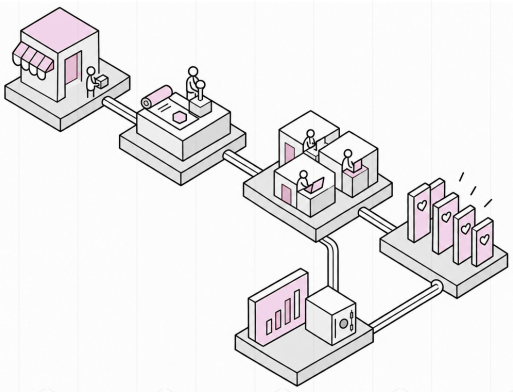

Figure 6: The Influence marketplace, left to right: a project books a campaign, the campaign is signed and anchored on chain, creators publish native content, results are measured, and rewards flow back to the creators who delivered.

6.2 The four roles

Role	What they do on Influence
Advertisers	Any project (app, game, shop, brand, service) that wants native promotion. Agrees a campaign: platforms, target market, budget, timing, creative, pay model.
Miners (creators)	Operators of one or several AI personas, each with its own niche and language, or human creators, on TikTok, Instagram and X. Grow real audiences, publish disclosed sponsored content when a campaign is live, and run a sealed measurement agent.
Validators	Independent auditors. Every epoch they request a sealed report from each miner, verify it, score authenticity and delivery, and publish weights.
Subnet owner	Curates and signs the campaign list, anchors it on chain, receives advertiser payments off-chain and uses them to buy back the subnet's alpha token.

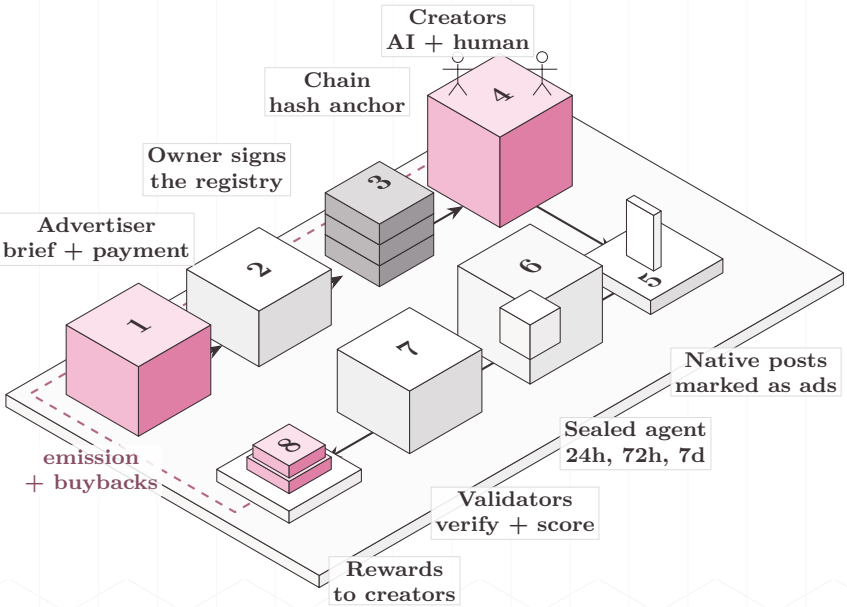

Figure 7: Lifecycle of a campaign, in eight stations. Solid arrows: briefs, content and reports; dashed arrow: value returning to creators as emission and buybacks.

6.3 A campaign, step by step

1. **Brief.** The advertiser and the owner agree the campaign: platforms, target countries, start and end, minimum creator quality, the approved creative, and the pay model.
2. **Payment.** The advertiser pays the owner, in fiat or TAO. The subnet's code never handles advertiser money.
3. **Signed registry.** The owner adds the campaign to a list called the *campaign registry*, signs it with the subnet owner key and writes its fingerprint (a hash) on chain. Validators and agents reject any list whose signature or fingerprint doesn't match, so nobody can change a campaign once it is published.
4. **Delivery.** Creators who opt in publish native videos or posts that match the approved creative, and carry the ad disclosure.
5. **Measurement.** The sealed agent registers each post and measures it after 24 hours, 72 hours and 7 days through the platform's official API.
6. **Scoring and reward.** Validators score the deliveries; the creators who delivered see their share of the miners' emission rise over the following epochs.
7. **Proof for the advertiser.** The agent can produce the list of post links for the campaign, encrypted so that only the advertiser can open it.

6.4 Two ways to pay

	Flat (fixed slots)	Performance
The advertiser buys	A fixed number of vetted placements	Measured reach and engagement
Who gets paid	The first N eligible creators to publish	Every eligible creator, in proportion to results
Best for	Launch waves, guaranteed presence	Awareness, conversation, virality
Concentration limit	$1/N$ per creator by construction	25% of a campaign per creator

With performance pricing, the advertiser decides what each signal is worth: a view, a like, a comment, a share. A brand that cares about conversation can value comments far above views. Each creator's results are then weighted by their authenticity score and by how much of their audience lives in the countries the campaign targets.

Why this is attractive to advertisers

You write one brief and it reaches many independent creators on three platforms. The results come from the platforms, not from the people you are paying. Posts without a disclosure, or that stray from the brief, are never paid, and no single creator can take more than a quarter of a performance budget.

7 Trust layer: sealed, private measurement

7.1 The core question: who measures?

Every advertising market comes down to one question: whose numbers do you believe? Our rule is simple. **The person who gets paid never touches the numbers.** The measuring is done by a small program running inside a *trusted execution environment* (TEE). Think of it as a computer sealed at the hardware level: the person who owns the machine can't read its memory or change what it does.

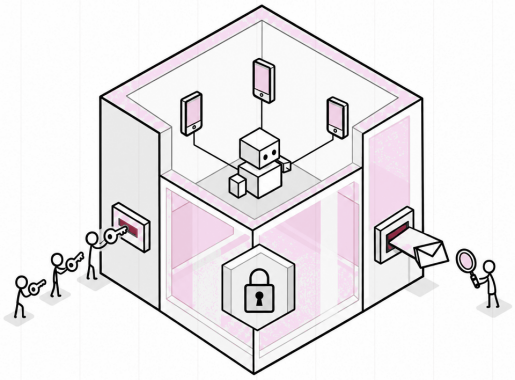

Figure 8: Confidential measurement: creators hand access to a sealed vault; the robot inside reads the official platform data; the auditor outside receives only a sealed, anonymous report.

7.2 How it works, without the jargon

1. **The creator connects the account** through the platform's own login screen (Instagram, TikTok or X). The access key lands *inside* the sealed machine, not on the miner's computer, and can be revoked by the creator at any time on the platform.
2. **The agent reads official data only.** It uses the platforms' official APIs. No scraping, no data brokers, no shared passwords.
3. **The hardware signs its work.** The sealed machine (Intel TDX, run with the open-source dstack framework [24]) produces a cryptographic certificate, called an attestation, proving which exact software produced the report and that it was not modified.
4. **Validators check the certificate.** Each validator keeps a public list of approved agent versions. A report from any other software, an old report replayed, or a report presented by the wrong miner scores zero.

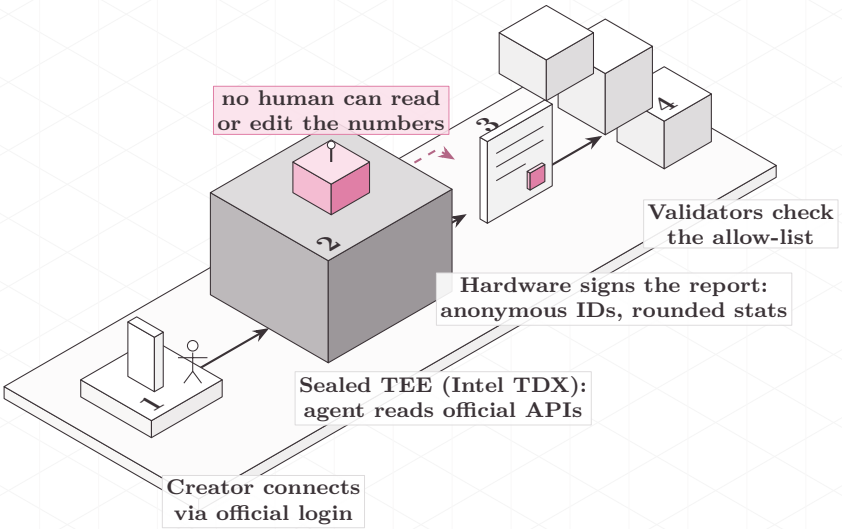

Figure 9: The trust layer in four steps. The access key lands inside sealed hardware; only an attested, anonymised report leaves it, and validators accept it only from approved software.

7.3 Private by design

Validators never find out which accounts a miner runs. What they get is an anonymous ID for each account, made with a key that never leaves the sealed machine, plus rounded statistics: follower counts

in buckets of about 9%, engagement shares, and an anonymous fingerprint of who engages. That turns out to help everyone involved.

- **Creators** cannot be harassed, poached or copied through a public list of handles tied to payouts.
- **The network** avoids collusion: a validator cannot favour a friend's account or sell the data, because it does not know whose account it is.
- **Advertisers** receive the post links in encrypted form; nobody else can see which creators ran their campaign, and the network cannot be bypassed.

7.4 Honest scoring between validators

Validators are rewarded for agreeing with the honest consensus, which gives a lazy validator a reason to copy someone else's scores instead of doing the work. To stop that, Influence uses Bittensor's *commit-reveal* mechanism. Each validator's scores are locked for a while and only become readable once copying them would no longer help; the chain unlocks them on its own. The scoring is also fully deterministic: two honest validators given the same reports will always get the same result.

8 Authenticity engine: making fake reach unprofitable

8.1 The principle

Trying to catch every bot is an arms race nobody wins. We went after the economics instead: **faking reach should always cost more than it pays**. Every creator account gets an authenticity score Q between 0 and 1, and everything the account earns is multiplied by it. Q is built from six separate signals, each one taken from published research on fake followers and fraud [10, 25–27].

Signal	What it catches, in plain words	Max penalty
Engagement rate	Bought followers bring reach with almost no reactions; like-farms bring more reactions than an audience of that size can produce.	●●●●●
Growth spikes	Purchases appear as a sudden one-day jump in followers.	●●●●○
Commenter quality	Bought comments come from empty profiles: no picture, no posts, accounts a few days old.	●●●●●
Comment duplication	Bot pools repeat the same few phrases with very little variety.	●●●●●
Like-to-view ratio	Views that nobody liked, or likes that nobody viewed, fall outside the human range.	●●●●○
Benford's law	Naturally grown counts follow a known pattern of first digits; fabricated ones usually do not [25].	●●○○○

Filled cubes show how strongly each signal can lower Q (its floor: 0.04–0.2 = five cubes, 0.3 = four, 0.5 = two). A weak, noisy signal is allowed less weight.

There is one more check on top of these six. A **pod detector** looks for groups of accounts that like and comment on each other's posts in lockstep, a trick known as an *engagement pod*. It borrows the lockstep idea that Facebook researchers used against coordinated fake likes [26]. If an account is caught in a pod, its quality score is cut in half.

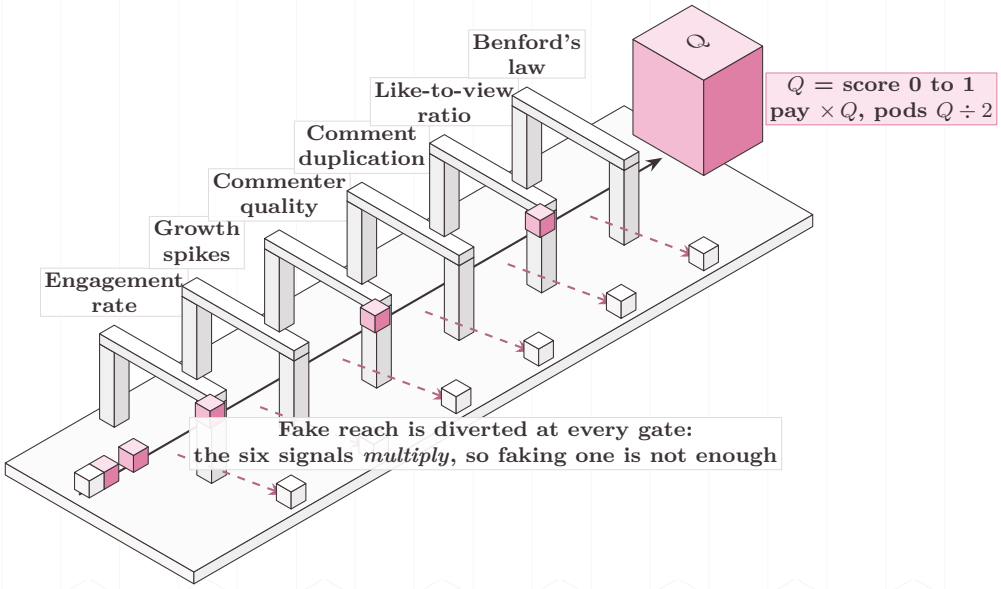

Figure 10: The authenticity engine. Every account passes six independent behavioural checks; each can lower its quality score Q, which multiplies everything the account earns.

8.2 Three choices behind the design

1. **Multiplicative.** The six signals multiply. A farm can fake one of them perfectly and still fail the other five. To fake all six at once you would have to build something very close to a real audience, and at that point you might as well build a real one.
2. **Counted twice.** Fake reach is discounted once in the community score and again in the final reward. So buying views leaves you *worse off* than not buying them at all.
3. **Never zero by accident.** Each signal has a floor. The evidence is statistical, and an honest creator can have an odd week.

8.3 No country is ever penalised

Click farms get caught for *what they do*, not for where they are. Every check looks at behaviour, and works the same way in every country. Geography only comes in at one point: when we match a creator's audience to the markets the advertiser chose. We also have an automated test that breaks the build if a country code ever shows up in the scoring rules [1].

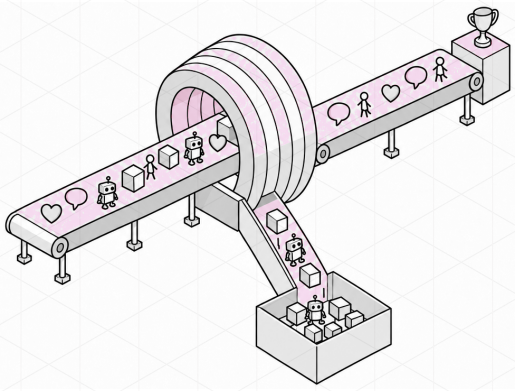

Figure 11: The authenticity filter: six independent checks let genuine engagement through and divert copy-paste comments, bots and bought followers.

8.4 Evidence from simulation

To see whether this holds up, we built a simulator that pushes 64 synthetic miners through the real scoring code for 30 epochs. Some are honest (small creators, mid-size creators, AI influencers). The others are bot farms, engagement pods, replay attackers and creators who skip the ad label. The table shows where the money ended up.

Miner type	Miners	Share of rewards
Honest, small creators	14	16.11%
Honest, mid-size creators	13	35.74%
Honest AI influencers	13	**37.22%**
Engagement pods	8	7.47%
No disclosure	2	1.56%
Bot farms	12	**0.0017%**
Replay attackers	2	0.00%

Source: reference run (seed 42, 30 epochs, 64 miners) in the Influence scoring specification [1]. Honest miners receive 89.08% in total; the owner and unallocated share is 1.89%.

9 Economics: how value flows

9.1 Two sources of value

1. **Network emission.** Like any Bittensor subnet, Influence gets a regular flow of newly minted alpha, split between the owner, validators and miners [23]. The size of that flow depends on how much the market wants the subnet's alpha [22].
2. **Advertiser revenue.** Advertisers pay the owner for campaigns, and the owner commits to spending that money on buying the subnet's alpha on the open market. When more brands advertise, the tokens creators and validators earn are worth more.

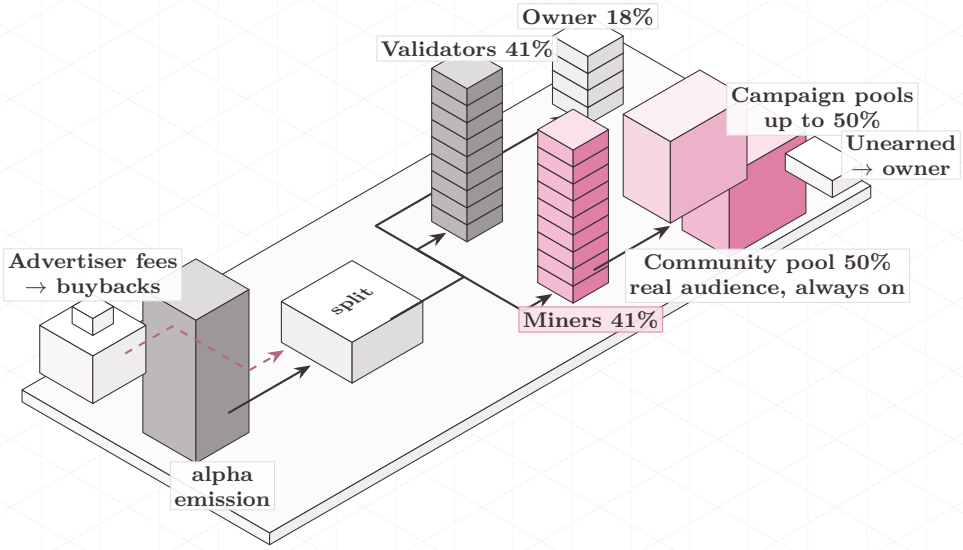

Figure 12: How value flows. Emission (and alpha bought back with advertiser fees) is split between owner, validators and miners; the miners' share feeds a community pool and the campaign pools.

9.2 How the miners' share is divided

Pool	Who earns it and why
Community pool (50% by default)	Paid to every creator for the genuine audience they already have, campaign or not. It keeps supply on the network, so that advertisers always find creators ready.
Campaign pools (up to 50%)	Paid to the creators who delivered each live campaign, under the flat or performance model.
Unallocated	Any campaign budget that no eligible creator earned goes to the owner, instead of overpaying a lone creator.

A creator's share of the community pool grows with the *logarithm* of their genuine reach. In plain

terms, a creator with ten times the audience earns more, but not ten times more, so one giant account can't swallow the pool. The pool also rewards posting regularly, about three times a week. Earnings are smoothed over several weeks, which means a lucky week doesn't make you rich, a bad week doesn't ruin you, and a one-off spike can't be cashed out.

9.3 A worked example

Our specification walks through a complete campaign, and an automated test checks that the code gives exactly these numbers [1]. It is a performance campaign aimed at France (80%) and Belgium (20%). Comments are worth ten times as much as views. Five creators take part:

- one forgot to mark the post as an ad, and another posted a video that strayed too far from the brief. **Neither earns anything** from the campaign;
- the one with the most raw engagement had a low authenticity score and an audience that was half American, so after weighting it finished *behind* a smaller French creator with a cleaner audience;
- that left three eligible creators. Each was capped at 25% of the campaign, and the quarter nobody earned went back to the owner.

That one example covers most of the design. Breaking the rules gets you nothing. Authenticity scales what you earn. A relevant audience is worth more. And nobody gets to take the whole budget.

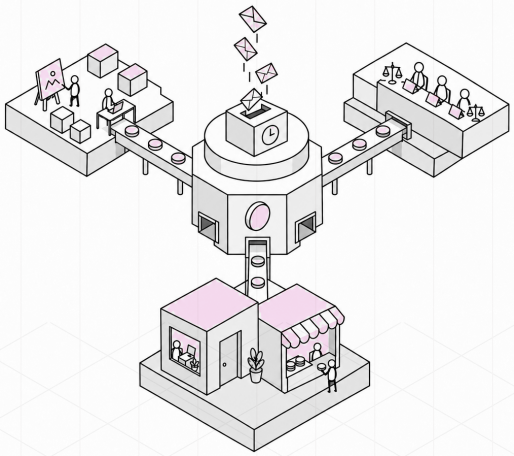

Figure 13: The reward engine: emission flows to creators who delivered, to validators who scored honestly, and to the owner, while sealed votes are revealed only after the copying window.

9.4 Incentives by participant

Participant	Best strategy under the rules
Creators	Build real audiences, post regularly, disclose every ad, deliver on brief. Buying followers lowers earnings.
Validators	Score honestly and exactly as specified: deviating from the shared, deterministic result gets a validator clipped by consensus and lowers its rewards.
Advertisers	Set clear briefs and choose the pay model that matches the goal: flat for presence, performance for measured reach.
Owner	Grow advertiser demand and run buybacks: more campaigns mean more value for everyone holding or earning alpha.

10 Use cases: who advertises on Influence

A campaign is really just a signed brief, so any project that can say what it wants people to see can use Influence. Here are a few of the campaigns we have in mind.

Project	Campaign idea	Suggested setup
Product launch	Dozens of short videos and posts by AI personas in the week a product comes out, each clearly marked as sponsored.	Flat, 20–40 slots, TikTok and Instagram.
Mobile app or game	"I tried this for a week" style vertical videos showing real gameplay or app use.	Performance, weighted on views and shares.
E-commerce brand	Unboxing and try-on videos in several languages, matching approved product shots.	Performance, target countries set to shipping markets.
AI or SaaS startup	Short demos and use-case posts from tech-niche creators.	Performance, weighted on comments (conversation).
Local business or event	A burst of local-language posts from creators whose audience is in the target city or country.	Flat, small slot count, geo-targeted.
Brand without a content team	Generates a month of videos, packshots and banners in the studio, then sends the best ones to creators.	Studio, then a performance campaign.

10.1 What an advertiser gets

- Native, disclosed posts from many independent creators, human or AI, on TikTok, Instagram and X.
- Numbers taken at 24 hours, 72 hours and 7 days from the platforms' official APIs, inside sealed hardware.
- An encrypted list of post links that only the advertiser can open.
- Access to the creative studio, to make the videos, photos and banners for a campaign or for its own channels.
- No bill for posts that skip the ad disclosure, stray from the brief or go up outside the campaign window, and no bill for fake reach.

10.2 What a creator gets

- A base income for the real audience they already have, campaign or not.
- Campaigns to join without negotiating each one.
- Privacy: validators never see which accounts are theirs.
- A fair shot: no penalty for where they live, and a 25% cap per creator, so a newcomer can still win a share of a big campaign.

11 Market opportunity

11.1 A large and growing market

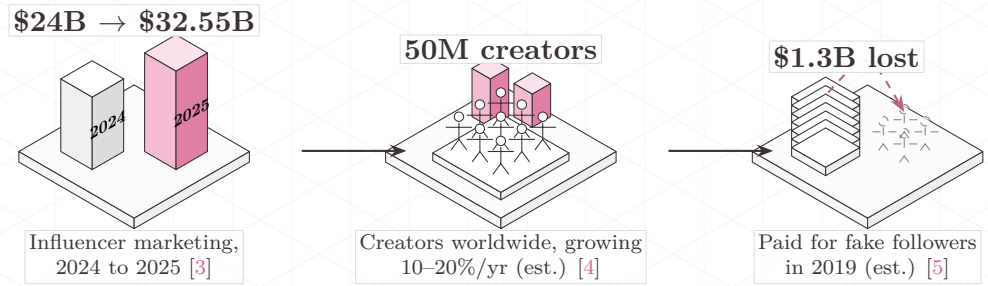

Figure 14: The market in three numbers. Spending on creators keeps rising, there are more creators every year, and a real share of the money still goes to audiences that do not exist.

Influencer Marketing Hub puts the global influencer marketing market at USD 32.55 billion in 2025, up from USD 24 billion a year earlier [3]. Goldman Sachs Research counts about 50 million creators worldwide and expects that number to grow by 10 to 20% a year. It also expects the creator economy to roughly double, from USD 250 billion to USD 480 billion, by 2027 [4].

11.2 Where Influence fits

We don't need to win the whole market for this to be worth doing. We are going after four groups that agencies and today's marketplaces serve badly.

1. **The long tail of advertisers.** Startups, apps, indie games and small brands that need native promotion but cannot afford agency minimums.
2. **Performance-minded brands.** Advertisers who like creator content but won't pay on the strength of a screenshot.
3. **Brands that need content, not just reach.** Teams that would otherwise pay one tool to make their ads and an agency to place them.
4. **AI-native supply.** People running AI personas who want to earn from a real audience without negotiating every single deal.

11.3 The companies we are measured against

Two kinds of companies already sell part of what Influence offers. On one side are AI content tools, which make ads but don't place them. On the other are influencer platforms, which find creators but leave the content and the proof of results to someone else. The first group is growing faster than almost anything else in software.

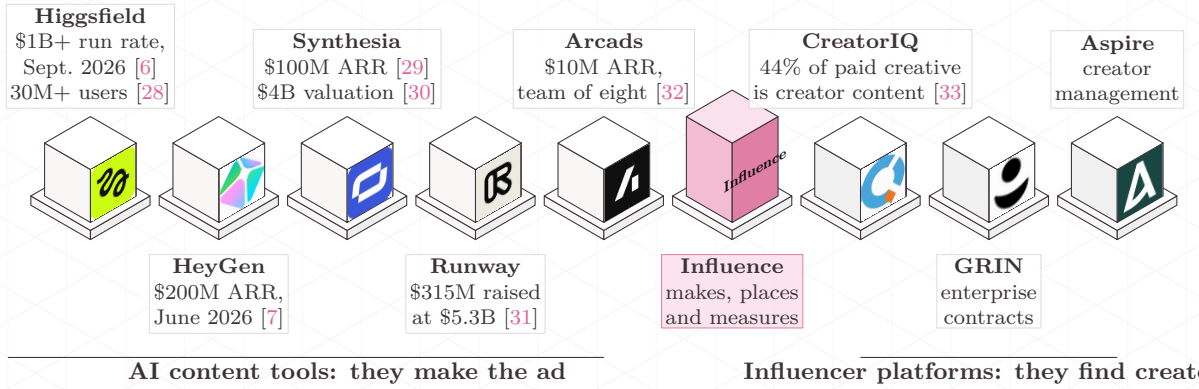

Figure 15: The companies we are measured against. AI studios make the content but do not place it; influencer platforms find creators but leave the content and the proof of results to someone else. Influence sits between the two. Logos are trademarks of their respective owners, shown only to identify the companies.

None of them closes the loop. Higgsfield or Arcads will give a brand a good video, but the brand still has to find an audience for it. CreatorIQ will find creators, but it won't make the ad, and the results still come back as the creator's own report. Influence does the three steps in one place: make the content, place it with creators who have real audiences, and pay on numbers read straight from the platforms.

11.4 How we compare with agencies and marketplaces

	Traditional agency or marketplace	Influence
Metrics	Self-reported screenshots or platform exports	Measured in sealed hardware, attested
Fake-reach protection	Manual vetting, third-party tools	Six-signal authenticity engine and pod detection, built into pay
Creator supply	Human creators, slow to scale	AI and human creators, incentivised by network emission
Disclosure	Contractual promise	Hard scoring gate
Creator privacy	Handles shared with the buyer and the platform	Anonymous to validators; links encrypted to the advertiser
Rules	Set by one company	Open specification, deterministic scoring, on-chain anchors

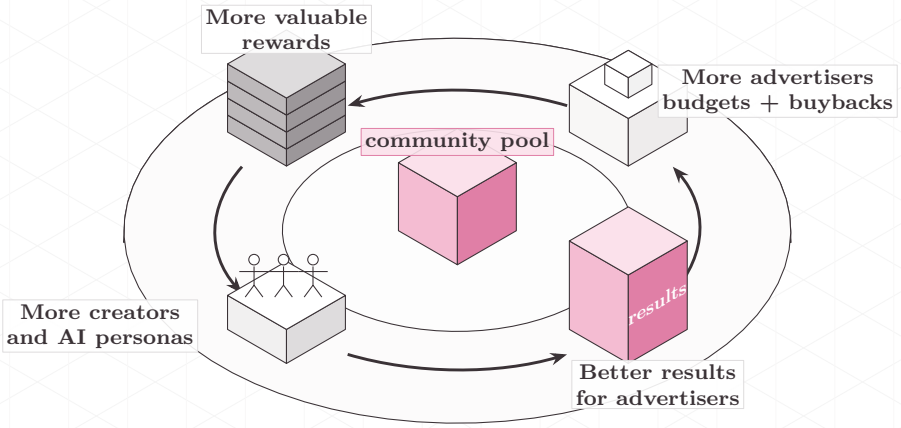

Figure 16: The flywheel. Demand funds rewards, rewards attract genuine supply, supply delivers results, results bring demand. The community pool starts the wheel before campaigns arrive.

11.5 The flywheel

More advertisers → more campaign budget and buybacks → **more valuable rewards** → more creators and AI personas building real audiences → **more and better supply** → better results for advertisers → **more advertisers**.

Every marketplace has a chicken-and-egg problem at the start. Ours is solved by the community pool, which pays creators for their real audience before any campaign exists. When the first advertisers arrive, the creators are already there.

12 Roadmap

12.1 What exists today

Version 0.1.0 of the open-source reference implementation is already written and tested [1]. It contains:

- the scoring engine (authenticity, community, pods, campaigns), pinned by golden test vectors;
- the sealed measurement agent for Instagram, TikTok and X, with hardware attestation;
- the validator, with time-locked commit-reveal of weights;
- the reference miner;
- the operations bundle (containers, service files, example configurations, local end-to-end test) and a deterministic simulator.

12.2 What comes next

Here is what we plan to build next.

Track	Goal
Creative studio	Open the generation studio to brands: videos, photos, banners and voice-overs from one brief, linked to campaign booking.
Advertiser portal	A self-serve interface for briefs, creative upload and reporting.
On-chain escrow	Move campaign funds into escrow released against attested deliveries, reducing trust in the owner.
More platforms	YouTube and others, where official APIs expose the signals the scoring needs.
Zero-knowledge proofs	Let a creator prove a metric to an advertiser without revealing the account (research).
Reproducible builds	One-command verification that the agent software matches the approved version.
Audits	Independent review of the scoring thresholds on real data and of the attestation path.

13 Conclusion

Ads work when people trust whoever is delivering them. For a lot of people today, the ones who skip pre-rolls and scroll past banners, that person is a creator: someone who shows up in their feed, speaks their language and talks about things they care about. The research points the same way again and again. Personal recommendations are the most trusted form of advertising [2], credible creators move people to buy [12, 13], and the money spent on them keeps growing [3, 4].

What has been missing is the plumbing. There is no open place where any project can book native posts across TikTok, Instagram and X, pay only for what real people saw, and get numbers that nobody in the chain was able to edit. That is what we are building.

Influence brings together three pieces that already exist but had never been combined: AI creators who can supply content in volume, sealed hardware that reads the numbers straight from the platforms, and Bittensor's open market for paying whoever does the work best. On top of that sit simple rules. Fake reach costs more than it earns, an undisclosed ad is worth nothing, and nobody learns which accounts a creator runs.

The studio makes the offer complete. A brand that has no content yet can generate it on the network, and a brand that has content can get it in front of real people. The companies that sell only one of those two things are already among the fastest-growing in software [6, 7].

The short version

We want buying creator posts to be as easy as buying search ads, with results you can check and no reason for anyone to fake them.
